## Research Achievements

As described in the research proposal section, block polymers with incompatible components naturally form periodic patterns in condensed state. These multiphase structures vary their morphologies depending on molecular parameters such as block chain connectivity and the degree of molecular asymmetry. This section introduces and describes the principal achievements brought by Matsushita's research group. The common feature of each section from the viewpoint of molecules is "frustration included in the system" introduced variously by complex molecular design. The main text is written along with slides attached.

### **1. The superlattice structures created by symmetric ABC linear terpolymers(slide #1)**

The centered B block chains in ABC linear block terpolymers have to adopt bridge conformation in bulk and the B chains are forced to be suffered from weak stress, and hence they naturally give featured structures. A variety of compositional change is possible, but here we focus on "symmetric" molecules whose volume fractions of A and C chains are the same each other. Polymer species adopted are **I(polyisoprene)**, **S(polystyrene)** and **P(poly(2-vinylpyridine))**, and many ISP terpolymers were prepared based on the anionic polymerizations under vacuum. The morphologies observed for symmetric terpolymers, whose volume fractions of I and P block are almost the same, are shown in the slide #1. Four structures, i.e., three-phase four-layered lamellar structure, **tricontinuous gyroid structure**, a cylindrical one with tetragonal symmetry and spherical structure of the CsCl type, can be seen from left to right with increasing the fraction of the center S block. It should be noting the fact that all these have the feature of **the superlattice structures**, in which I and P domains can be switched mutually.

### **2. Tricontinuous double diamond structure from binary blends of linear ABC triblock terpolymers (slide #2)**

As displayed in the slide #2, two asymmetric ISP terpolymers were prepared and the structures of their binary blends were observed, where the overall compositions were designed to keep symmetry. **Four-branched double diamond structure** was stably observed by realizing weak localization of two molecules on the phase-separated surface, in contrast to the three-branched double gyroid structure for monodisperse symmetric molecules as introduced in the previous section. This structure is conceived to be formed to earn the conformational entropy for the end block chains by scarifying both the surface energy and junction-placement entropy. This symmetric but unusual morphology was created under weak stress due to the present molecular design.

### **3. Periodic and aperiodic tiling patterns from ABC star molecules(slides #3 and #4)**

If each end of three different polymer chains are connected at one junction point, we can get **ABC star molecules**, whose junction points have to be aligned on lines not on surfaces, and therefore block chains are restricted to stay within the very frustrated spaces. And they naturally form rod-based morphology. If we explore to check the order the cross-sectional view, we naturally meet the two-dimensional space-sharing patterns, i.e., tilings. The slide #3 shows schematic expression of the self-assembly manner of this type of molecules, and several examples of the observed patterns are assembled on the right, which includes many **periodic Archimedean tiling patterns** and also an aperiodic pattern at the center. This characteristic one in a pentagon has the feature of **aperiodicity with dodecagonal symmetry** as shown in the slide #4 in detail. This non-classic ordered pattern was first discovered in metal alloy in 1982 by Prof. D. Shechtman, who was honored as a single Nobel Prize laureate in chemistry section in 2011, whereas our discovery of quasi-crystal with mesoscopic tile size in 2007 was in the memorial year of silver jubilee of Shechtman's first discovery in 1982.

#### 4. Non-classical structures in tetrablock terpolymers of the A<sub>1</sub>BA<sub>2</sub>C type(slide #5)

Tetrablock terpolymers of the A<sub>1</sub>BA<sub>2</sub>C type naturally hold frustration in molecules themselves since A<sub>1</sub> and A<sub>2</sub> have to play deferent roles in self-assembly, and so forth they represent featured morphologies. The slide #5 displays the double hexagonal and tetragonal structures from S<sub>1</sub>IS<sub>2</sub>P terpolymers at the left-hand side, while **the 3.3.4.3.4 AT structure** and another **quasicrystalline tiling with dodecagonal symmetry** from well-annealed binary blends of terpolymers are compared at the right-hand side of the slide. These non-classical structures have been found to appear covering wide composition region, indicating that these are evidently thermodynamically stable structures. These results are owing to the frustrated molecular systems adopted in the present study.
